

SHEATH FOR USE WITH AN EMBOLIC PROTECTION FILTERING DEVICE

Field of the Invention

The present invention pertains to embolic protection filtering devices. More particularly, the present invention pertains to sheaths for delivering and retrieving 5 embolic protection filtering devices.

Background

Heart and vascular disease are major problems in the United States and throughout the world. Conditions such as atherosclerosis result in blood vessels becoming blocked or narrowed. This blockage can result in lack of oxygenation of the 10 heart, which has significant consequences since the heart muscle must be well oxygenated in order to maintain its blood pumping action.

Occluded, stenotic, or narrowed blood vessels may be treated with a number of relatively non-invasive medical procedures including percutaneous transluminal angioplasty (PTA), percutaneous transluminal coronary angioplasty (PTCA), and 15 atherectomy. Angioplasty techniques typically involve the use of a balloon catheter. The balloon catheter is advanced over a guidewire such that the balloon is positioned adjacent a stenotic lesion. The balloon is then inflated and the restriction of the vessel is opened. During an atherectomy procedure, the stenotic lesion may be mechanically cut away from the blood vessel wall using an atherectomy catheter.

20 During angioplasty and atherectomy procedures, embolic debris can be separated from the wall of the blood vessel. If this debris enters the circulatory system, it could block other vascular regions including the neural and pulmonary vasculature. During angioplasty procedures, stenotic debris may also break loose due to manipulation of the

blood vessel. Because of this debris, a number of devices, termed embolic protection devices, have been developed to filter out this debris.

Brief Summary

The present invention pertains to sheaths that may be used for delivering and/or retrieving embolic protection filtering devices. In at least some embodiments, the sheath may include a proximal portion and a distal portion. The distal portion may be expandable and may include a bulbous member. Additionally, the sheath may include structural support in a number of different forms. These and other structural features and characteristics are described in more detail below.

Detailed Description

The following description should be read with reference to the drawings wherein like reference numerals indicate like elements throughout the several views. The detailed 20 description and drawings illustrate example embodiments of the claimed invention.

Figure 1 is partial cross-sectional plan view of an example sheath 10 that may be used to facilitate the delivery and/or retrieval of an embolic protection filter 12. When used for retrieval of filter 12, sheath 10 may be advanced through a blood vessel 14 over

a guidewire 16 or other medical device having filter 12 coupled thereto. Further distal advancement of sheath 10 may allow filter 12 to become collapsed and disposed within sheath 10. Sheath 10 and filter 12 can then be proximally retracted from vessel 14. When sheath 10 is used for delivery, filter 12 may be collapsed and disposed within 5 sheath 10, sheath 10 can be advanced through the vasculature to an appropriate location, and sheath 10 can be proximally retracted or otherwise configured so that filter 12 expands within vessel 14. The remaining discussion focuses more heavily on some of the characteristics, features, and uses of sheath 10 pertaining to filter retrieval. However, it can be appreciated that a number of these features may analogously apply to filter 10 delivery.

Frequently, intravascular procedures may involve the placement of a stent 18 in blood vessel 14 to open or expand a stenosis 20. It may be desirable for the clinician to include the use of filter 12 when performing the intravascular stent placement procedure. Accordingly, it may be necessary for the clinician to retrieve filter 12 after stent 18 has been placed. Because it may be desirable for a retrieval device to have the greatest possible 15 outside diameter in order to allow the filter to be disposed therein, and because this large outside diameter may cause the retrieval device to contact stent 18, it is possible that the retrieval device may disrupt the position of stent 18. Disrupting the position of stent 18 may undermine its function and efficacy. Therefore, it may be desirable to use retrieval 20 devices that are configured so as to be less likely to disrupt stent 18.

Retrieval may often include disposing a portion of the filter in the retrieval device. However, because the filter may be enlarged due to the amount of debris it is holding, the filter itself may catch on stent 18. Therefore, it may be desirable for a retrieval device to

be adapted and configured to fully encapsulate the filter, thereby eliminating the possibility that the filter may disrupt stent 18.

Sheath 10 is an example of one such device. In at least some embodiments, sheath 10 may include a proximal region 22, a distal region 24, and one or more lumens 5 (not shown in Figure 1, but some examples of lumens that may be appropriate are illustrated in Figures 4 and 5). Distal region 24 may include a bulbous region or member 26. Bulbous region 26 may be shaped or otherwise configured to have one or more gradual steps in outside diameter. The transition in outside diameter may be from the generally smaller outside diameter adjacent distal region 24 to the generally larger 10 outside diameter adjacent bulbous region 26. For example, bulbous region 26 may include a proximal tapered surface 28 and a distal tapered surface 30. Tapered surfaces 28/30 may allow sheath 10 to more easily pass stent 18 in either the proximal or distal direction (depending on whether sheath 10 is being proximally retracted or distally advanced along guidewire 16) by allowing the transition in outside diameter to be more 15 gradual than other devices having a blunted end, which could “catch” on stent 18 and disrupt it.

Distal region 24 may be adapted for having filter 12 disposed therein, for example in a lumen extending through distal region 24. In at least some embodiments, distal region 24 is appropriately sized and configured for having filter 12 fully encapsulated 20 therein during retrieval of filter 12. Additionally, because a substantial amount of debris may accumulate and become contained within filter 12, distal region 24 of sheath 10 may be subjected to a relatively large force (e.g., due to the size or weight of filter 12) when attempting to encapsulate or otherwise dispose filter 12 within sheath 10. This force, if

not properly absorbed, could lead to the distal end of a retrieval device being expanded, collapsed, or even prolapsed, which may increase the likelihood that the retrieval device may contact and disrupt stent 18. Therefore, it may be desirable for distal region 24 of sheath 10 to be structurally reinforced, so as to more easily absorb these forces produced

5 when encapsulating or otherwise disposing filter 12 within sheath 10. In at least some embodiments, bulbous region 26 may have an increased thickness, which may add additional structural support to distal region 24 of sheath 10.

In at least some embodiments, sheath 10 may include an expandable or enlargeable distal mouth 31 disposed adjacent distal region 24. The expandability of mouth 31 may be at least partially due to the material composition of sheath 10. For example, the materials used to construct sheath 10 (e.g., adjacent mouth 31) may be substantially elastic and/or include elastomeric polymers. Some examples of suitable elastic materials may include elastomeric polyamides, polyether-ester elastomers, and the like as well as other materials including those listed herein. Mouth 31 may be configured

10 to reversibly enlarge in order for sheath 10 to engulf or otherwise accommodate filter 12 therein. For example, Figure 1A illustrates sheath 10 where it has been distally advanced toward filter 12 and where mouth 31 is enlarged to an expanded configuration or position so as to allow filter 12 to pass therein. Further distal advancement of sheath 10 allows

15 filter 12 to become essentially engulfed within distal region 24 of sheath 10 as shown in Figure 1B. After sheath 10 has passed over filter 12, mouth 31 can close or otherwise

20 resume its previous non-expanded or basal configuration.

Figure 2 is a partially cut away perspective view of another example sheath 110, that is similar to other sheaths described herein, where distal region 124 (and bulbous

member 126) may be reinforced by including one or more braids. For example, sheath 110 may include an inner member 132, which may or may not include any braiding. A first braided layer 134 may be disposed on inner member 132. A second braided layer 136 (as well as additional braided or other layers) may be disposed on first braided layer 134. The exact arrangement and position of layers included in sheath 110 may vary. For example, the various braided layers may be disposed along essentially the entire length of sheath 110 (including proximal region 122) or any region or combination of regions including at bulbous member 126 and, in some embodiments, at bulbous member 126 only. Additionally, the layers or may be disposed intermittently so that the various regions may include differing numbers or configurations of layers. It can be appreciated that any of the other structural features or other characteristics of any of the other sheaths described herein, for example having an expandable distal mouth similar to what is disclosed above, may be included with sheath 110.

Figure 3 is a more detailed view of an example braided layer (in this case braided layer 134) that is appropriate for any of the embodiments of sheaths disclosed herein. Braided layer 134 may include a plurality of fibers, for example, a first fiber 138, a second fiber 140, a third fiber 142, and a fourth fiber 144. Of course, including four fibers in braided layer 134 is not intended to be limiting as any appropriate number of fibers may be utilized without departing from the spirit of the invention.

Fibers 138/140/142/144 can be made of any suitable materials including metals, metal alloys, polymers, or the like, or combinations or mixtures thereof. Some examples of suitable metals and metal alloys include stainless steel, such as 304v stainless steel; nickel-titanium alloy, such as nitinol, nickel-chromium alloy, nickel-chromium-iron

alloy, cobalt alloy, or the like; or other suitable material. Some examples of suitable polymers may include polytetrafluoroethylene (PTFE), ethylene tetrafluoroethylene (ETFE), fluorinated ethylene propylene (FEP), polyurethane, polypropylene (PP), polyvinylchloride (PVC), polyether-ester (for example a polyether-ester elastomer such 5 as ARNITEL® available from DSM Engineering Plastics), polyester (for example a polyester elastomer such as HYTREL® available from DuPont), polyamide (for example, DURETHAN® available from Bayer or CRISTAMID® available from Elf Atochem), elastomeric polyamides, block polyamide/ethers, polyether block amide (PEBA, for example available under the trade name PEBAK®), silicones, polyethylene, Marlex high-10 density polyethylene, Marlex low-density polyethylene, linear low density polyethylene (for example REXELL®), polyethylene terephthalate (PET), polyetheretherketone (PEEK), polyimide (PI), polyetherimide (PEI), polyphenylene sulfide (PPS), polyphenylene oxide (PPO), polysulfone, nylon, perfluoro(propyl vinyl ether) (PFA), other suitable materials, or mixtures, combinations, or copolymers thereof. In some 15 embodiments, fibers 138/140/142/144 can include a liquid crystal polymer (LCP) blended with other polymers to enhance torqueability.

Fibers 138/140/142/144, or portions thereof, may also be doped with or otherwise include a radiopaque material. Radiopaque materials are understood to be materials capable of producing a relatively bright image on a fluoroscopy screen or another 20 imaging technique during a medical procedure. This relatively bright image aids the user of sheath 10 in determining its location. Some examples of radiopaque materials can include, but are not limited to, gold, platinum, palladium, tantalum, tungsten alloy, plastic material loaded with a radiopaque filler, and the like.

In some embodiments, braided layer 134 may include combinations of fibers that include differing materials. For example, first fiber 138 may be a platinum wire and the remaining fibers 140/142/144 may have a polymeric composition. This configuration of fibers may be desirable for a number of reasons. For example, including a platinum first 5 fiber 138 allows sheath 110 to be visualized using conventional fluoroscopy techniques. Additionally, the choice of polymer used for remaining fibers 140/142/144 can be selected according to the characteristics desired for sheath 110. For example, relatively flexible polymers may be used in embodiments where flexibility is desired.

The shape, thickness, and other characteristics of fibers 138/140/142/144 may 10 also vary. For example, any single or combination of fibers 138/140/142/144 may include a generally round wire, a generally flat ribbon, other shapes, and the like. Similarly, the diameter or thickness of fibers 138/140/142/144 may vary. Some 15 embodiments include sets of fibers having the same diameter while other embodiments include sets of fibers having differing diameters. Additionally, some generally thick fibers (e.g., which may include metal and radiopaque fibers such as fiber 138) can be replaced by a set of micro-cables 138' as illustrated in Figure 3A. These micro-cables 138' are sets of wires that, when considered together as a unit, have a cross-sectional diameter that approximates fiber 136. However, micro-cables 138' may have physical 20 characteristics (e.g., flexibility) that more closely resemble those of the individual wires. Thus, this feature may help maintain flexibility by replacing a thick, relatively stiff fiber with a set of micro-cables 138' that, individually, may be relatively flexible.

Manufacturing of sheath 110 may include convention braiding techniques and equipment. In some embodiments, multiple fibers (e.g., fibers 138/140/142/144) may be

added to a braiding bobbin, which may create a “multi-ended” braid. For example, fibers 138/140/142/144 can be added to the braiding bobbin and braided onto an appropriate substrate. The appropriate substrate may vary and could include a mandrel, mold, tube similar to inner member 132, and the like. It should be noted that some embodiments, 5 like one of the examples described above where first fiber 138 is a platinum wire, it may still be appropriate to add all of the fibers 138/140/142/144 to a single bobbin, for example, by simply adding a platinum wire (e.g., fiber 138) to a bobbin having multiple polymeric fibers (e.g., fibers 140/142/144) to create a multi-ended braid that includes fibers of differing materials.

10 Another example sheath 210 is illustrated in Figure 4. Sheath 210 is similar to other sheaths described herein, except that it includes a frame or coil 244. In some embodiments, coil 244 may be disposed adjacent bulbous region 226 and may provide structural support. However, coil 244 may be disposed at any appropriate location including distal region 224, the proximal region (not shown), combinations of regions, or 15 the entire length of sheath 210. Other types of frame structures may be substituted with coil 244 without departing from the spirit of the invention. For example, appropriate substitutes for coil 244 may include a branching or non-branching frame, a leaf spring shaped frame, a stent-shaped frame, or other suitable structures. Figure 4 also shows that a lumen 245 may extend through sheath 210 as well as any of the other sheaths described 20 herein. Lumen 245 may allow sheath 210 to advance along guidewire 16 and have at least a region that is sized appropriately for having filter 12 disposed therein.

Another example sheath 310 is illustrated in Figure 5. Sheath 310 is similar to other sheaths described herein and may include proximal region 322, distal region 324, ,

bulbous region 326, and lumen 345. However, distal region 324 and proximal region 322 may comprise separate structures that are attached by any one of a number of techniques. For example, proximal region 322 and distal region 324 may be attached by adhesive bonding with or without the inclusion of appropriate tie layers. Alternatively, distal 5 region 324 may be molded (e.g., insert molded) onto proximal region 322. Essentially any other appropriate molding or bonding technique may be used without departing from the spirit of the invention.

In some embodiments, proximal region 322 may comprise a typical retrieval sheath. According to this embodiment, lumen 345 may be in fluid communication with 10 the lumen of the typical retrieval device. Distal region 324 may be a structure that is attachable to these typical retrieval devices in order to provide sheath 310 with desirable characteristics such as those described herein. This feature allows distal region 324 to be similar to an “adaptor” or other refining device that can be used to provide existing devices with at least some of the desirable features attributable to distal region 324.

15 The material composition of distal region 324 (as well as any of the components of sheath 310) may include any of the materials listed herein including metals, metal-alloys, and polymers. For example, distal region 324 may be comprised of silicone or essentially any appropriate durometer. According to this embodiment, distal region 324 may be adhesively bonded to proximal region 322 using appropriate adhesives or tie 20 layers. Alternatively, distal region 324 may be comprised of injection-moldable materials such as DURAFLEX™, linear block copolymer such as KRATON™, SUPERFLEX™, and the like.

Distal region 324 may also include any of the other structural elements described herein, for example, to provide structural support to distal region 324. For example, distal region 324 may include one or more braided layers, a coil, a frame, a stent-like structure, and the like. Distal region 324 may also include bulbous region 326. In some 5 embodiments, bulbous region 326 may provide distal region 324 with additional structural support by increasing the wall thickness of distal region 324. Additionally, bulbous region 326 or regions adjacent it may have a conical or funnel shaped inside diameter surface 346, which may make it easier for filter 12 to pass into distal region 324. Additionally, distal region 324 and/or bulbous region 326 may include a rounded or 10 generallyatraumatic distal end 348.

Additional structural strength may also include varying the wall thickness of distal region 324. For example, it can be seen in Figure 5 that distal region 324 may include lumen 345 defining an inside diameter of distal region 324. In some embodiments, variation in the inside diameter of distal region 324 correspond to variation 15 in the wall thickness of distal region 324. According to this embodiment, as the inside diameter decreases, the wall thickness of distal region 324 increases. Changes in wall thickness, similar to what is described above, may alter the compressive strength of distal region 324.

In some embodiments, the inside diameter of distal region 324 may gradually 20 taper in the proximal direction. This may correspond with increased wall thickness for distal region 324 in the proximal direction. This feature may help provide increase compressive strength adjacent some of the proximal positions of distal region 324, including positions where filter 12 may eventually become disposed. Additionally,

because the taper may be gradual, weak points that might otherwise have been created by pronounced steps in inside diameter can be reduced.

Bulbous member 326 may be defined or otherwise formed in a number of ways. For example, bulbous member 326 may be defined during the molding of distal region 5 324. Alternatively, bulbous member 326 may be defined by molding or otherwise coupling it to distal region. For example, bulbous member 326 may be defined by adhesively bonding or insert molding it to distal region 324.

Regardless of how bulbous member 326 is defined, it may vary in its shape and configuration. Figures 6-14 illustrate cross-sectional views of some examples of the 10 various shapes and configurations that may be for bulbous member 326. For example, Figure 6 shows that bulbous member 326 as being a single piece that may be integral with distal region 324 or be molded to or adhesively bonded to distal region 324. On the other hand, bulbous member 326 may include a plurality of subunits. For example, Figure 7 shows an alternative bulbous member 426 having two subunits 452a/b, Figure 8 15 shows bulbous member 526 having four subunits 552a/b/c/d, and Figure 9 shows bulbous member 626 including six subunits 652a/b/c/d/e/f. It can be appreciated that any number of subunits may be included in the various embodiments of the invention.

Figures 10 and 11 show that the subunits may have varying arrangements. For example, bulbous member 726 may include subunits 752a/b/c/d arranged in a swirling 20 pattern as shown in Figure 10. Alternatively, bulbous member 826 includes subunits 852a/b/c/d arranged on opposite sides and on top of one another as in Figure 11.

Figures 12-14 illustrate other example bulbous members that include ridges and voids. The number and arrangement of the ridges and voids may vary. For example,

bulbous member 926 of Figure 12 includes four ridges 954 and four voids 956 spaced between ridges 954. Similarly, Figure 13 illustrates bulbous member 1026 having five ridges 1054 and five voids 956. Finally, Figure 14 illustrates bulbous member 1126 having six ridges 1154 and six voids 1156. Of course the number and arrangement of 5 ridges and voids is not intended to be limited as the number and arrangement may vary from what is shown.

In some embodiments, other portions of the sheath may include ridges and voids. For example, Figure 15 illustrates another example sheath 1210 that includes ridges 1254 and voids 1256 disposed proximally of bulbous member 1226. The combination of 10 ridges 1254 and voids 1256 in sheath 1210 (as well as other structures disclosed herein) may be desirable by allowing sheath to expand adjacent voids 1256 while ridges 1254 impart the desired column strength for sheath 1210. According to this embodiment, including ridges 1254 and voids 1256 may allow sheath 1210 to more easily expand to “swallow” filter 12, while maintaining its column strength and integrity.

15 Another example sheath 1310 is shown in Figure 16. Sheath 1310 is similar to sheath 1210 (and other described herein), except that ridges 1354 and voids 1356 extend along bulbous member 1326 as well as positions proximally thereof. This feature may be desirable for reasons described above as well as other reasons. For example, including ridges 1354 and voids 1356 proximally of bulbous member 1326 may allow for greater 20 expansion of sheath 1310, which may allow filter 12 to more easily become encapsulated or otherwise disposed therein.

Sheath 1310 may also include a proximal member 1358. In some embodiments, proximal member 1358 may be configured to attach to a retrieval device, similar to what

is shown in Figure 5. According to this embodiment, distal region 1324 may have a lower profile than proximal member 1358, which may improve its ability to cross a stent, and include ridges 1354 and voids 1356 so as to be expandable to accommodate filter 12. Proximal member 1358 may then extend proximally from distal region 1324 and be 5 attachable to a retrieval device. Alternatively, proximal member 1358 may include the proximal region of sheath 1310. Accordingly, proximal member 1358 may be configured to extend proximally outside the body of a patient when using sheath 1310 to retrieve filter 12.

It should be understood that this disclosure is, in many respects, only illustrative. 10 Changes may be made in details, particularly in matters of shape, size, and arrangement of steps without exceeding the scope of the invention. The invention's scope is, of course, defined in the language in which the appended claims are expressed.
